

# **MACHINE LEARNING**

(Prediction of Acceptance of Admission into a University)

Summer Internship Report Submitted in partial fulfilment of the  
requirement for undergraduate degree of

**Bachelor of Technology**

In

**Computer Science and Engineering**

By

**Janjam Gayathri**

**221710313018**

Under the Guidance of

Assistant Professor

Department of Computer Science and Engineering  
GITAM School of Technology  
GITAM (Deemed to be University)  
Hyderabad-502329  
July 2020

## DECLARATION

I submit this industrial training work entitled “**PREDICTION OF ACCEPTANCE OF ADMISSION INTO A UNIVERSITY**” to GITAM (Deemed To Be University), Hyderabad in partial fulfilment of the requirements for the award of the degree of “**Bachelor of Technology**” in “**Computer Science and Engineering**”. I declare that it was carried out independently by me under the guidance of Asst. Professor, GITAM (Deemed to Be University), Hyderabad, India.

The results embodied in this report have not been submitted to any other University or Institute for the award of any degree or diploma.

Place: HYDERABAD

Janjam Gayathri

Date:

221710313018

GITAM (DEEMED TO BE UNIVERSITY)

Hyderabad-502329, India

Dated:

## **CERTIFICATE**

This is to certify that the Industrial Training Report entitled “**PREDICTION OF ACCEPTANCE OF ADMISSION INTO A UNIVERSITY**” is being submitted by Janjam Gayathri (221710313018) in partial fulfilment of the requirement for the award of **Bachelor of Technology in Computer Science Engineering** at GITAM (Deemed to Be University), Hyderabad during the academic year 2019-2020.

It is faithful record work carried out by her at the **Computer Science and Engineering Department**, GITAM University Hyderabad Campus under my guidance and supervision.

Assistant Professor  
Department of CSE

Head of Department  
Department of CSE

## ACKNOWLEDGEMENT

Apart from my effort, the success of this internship largely depends on the encouragement and guidance of many others. I take this opportunity to express my gratitude to the people who have helped me in the successful competition of this internship.

I would like to thank **Dr. N. Siva Prasad**, Pro Vice Chancellor, GITAM Hyderabad.

I would like to thank respected **Dr. Phani Kumar**, Head of the Department of Computer Science Engineering for giving me such a wonderful opportunity to expand my knowledge for my own branch and giving me guidelines to present an internship report. It helped me a lot to realize what we study for.

I would like to thank the respected faculties who helped me to make this internship a successful accomplishment

I would also like to thank my friends who helped me to make my work more organized and well-stacked till the end.

Janjam Gayathri  
221710313018

## **ABSTRACT**

Machine learning algorithms are used to predict the values from the data set by Splitting the data set in to train and test and building Machine learning algorithms models of higher accuracy to predict the values is the primary task to be performed on Cereals data set. My perception of understanding the given data set has been in the view of undertaking a student's requirement of for joining into a university

The aim of this research is to develop a system using machine learning algorithms, we will name it as Prediction of Acceptance of Admission into a University. It will help the students to identify the chances of their application to a university being accepted. Also, it will help them in identifying the universities which are best suitable for their profile and also provide them with the details of those universities. A simple user interface will be developed for the users to access the system. Keywords: Prediction of Acceptance; Machine Learning; Data Mining.

# **CHAPTER 1**

## **MACHINE LEARNING**

### **1.1 INTRODUCTION**

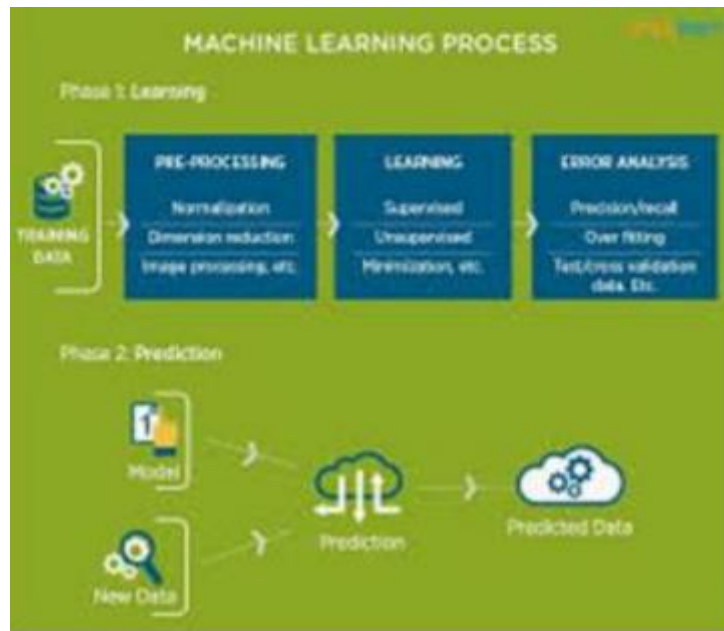

Machine Learning (ML) is the scientific study of algorithms and statistical models that computer systems use in order to perform a specific task effectively without using explicit instructions, relying on patterns and inference instead. It is seen as a subset of Artificial Intelligence (AI).

### **1.2 IMPORTANCE OF MACHINE LEARNING**

Consider some of the instances where machine learning is applied: the self-driving Google car, cyber fraud detection, online recommendation engines—like friend suggestions on Facebook, Netflix showcasing the movies and shows you might like, and “more items to consider” and “get yourself a little something” on Amazon—are all examples of applied machine learning. All these examples echo the vital role machine learning has begun to take in today’s data-rich world.

Machines can aid in filtering useful pieces of information that help in major advancements, and we are already seeing how this technology is being implemented in a wide variety of industries.

With the constant evolution of the field, there has been a subsequent rise in the uses, demands, and importance of machine learning. Big data has become quite a buzzword in the last few years; that’s in part due to increased sophistication of machine learning, which helps analyse those big chunks of big data. Machine learning has also changed the way data extraction, and interpretation is done by involving automatic sets of generic methods that have replaced traditional statistical techniques.

**Figure 1.2: The Process Flow**

## 1.3 USES OF MACHINE LEARNING

Earlier in this article, we mentioned some applications of machine learning. To understand the concept of machine learning better, let's consider some more examples: web search results, real-time ads on web pages and mobile devices, email spam filtering, network intrusion detection, and pattern and image recognition. All these are by-products of applying machine learning to analyse huge volumes of data.

Traditionally, data analysis was always being characterized by trial and error, an approach that becomes impossible when data sets are large and heterogeneous. Machine learning comes as the solution to all this chaos by proposing clever alternatives to analysing huge volumes of data.

By developing fast and efficient algorithms and data-driven models for real-time processing of data, machine learning can produce accurate results and analysis.

## 1.4 TYPES OF LEARNING ALGORITHMS

The types of machine learning algorithms differ in their approach, the type of data they input and output, and the type of task or problem that they are intended to solve.

### **1.4.1 Supervised Learning:**

When an algorithm learns from example data and associated target responses that can consist of numeric values or string labels, such as classes or tags, in order to later predict the correct response when posed with new examples comes under the category of supervised learning.

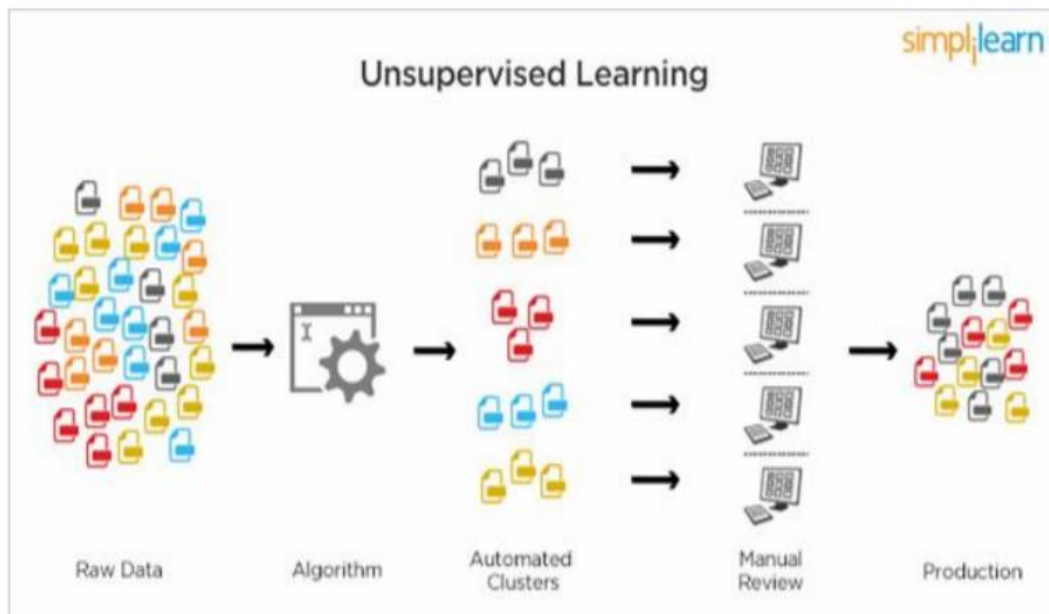

Supervised machine learning algorithms uncover insights, patterns, and relationships from a labelled training dataset – that is, a dataset that already contains a known value for the target variable for each record. Because you provide the machine learning algorithm with the correct answers for a problem during training, it is able to “learn” how the rest of the features relate to the target, enabling you to uncover insights and make predictions about future outcomes based on historical data.

Examples of Supervised Machine Learning Techniques are Regression, in which the algorithm returns a numerical target for each example, such as how much revenue will be generated from a new marketing campaign.

Classification, in which the algorithm attempts to label each example by choosing classification, such as determining whether or not someone will default on a loan. Choosing between more than two classes is referred to as multiclass classification.

### **1.4.2 Unsupervised Learning:**

When an algorithm learns from plain examples without any associated response, leaving to the algorithm to determine the data patterns on its own. This type of algorithm tends to restructure the data into something else, such as new features that may represent a class or a new series of uncorrelated values. They are quite useful in providing humans with insights into the meaning of data and new useful inputs to supervised machine learning algorithms.

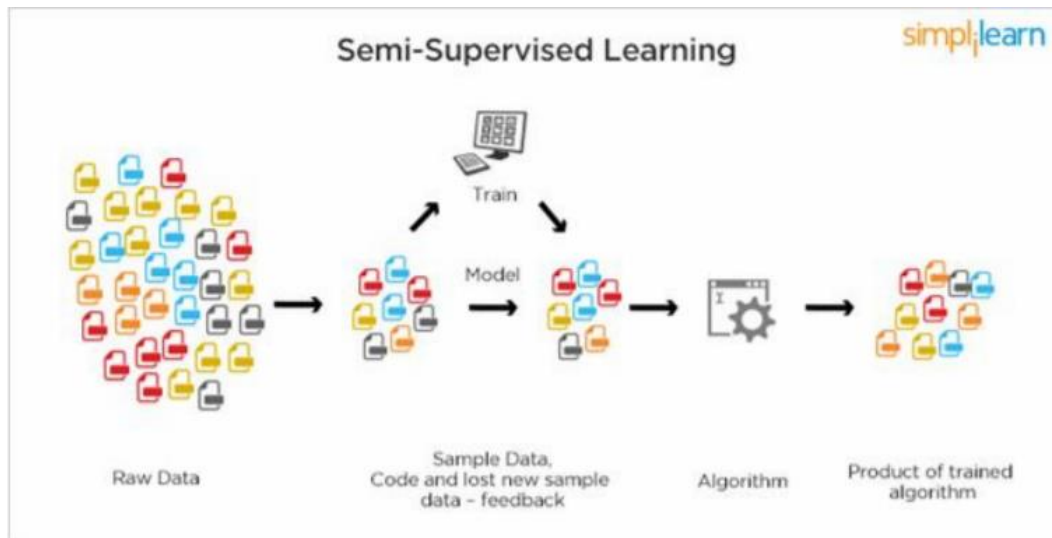

**Figure 1.4.2: Unsupervised Learning**

Popular techniques where unsupervised learning is used also include self-organizing maps, nearest neighbour mapping, singular value decomposition, and k-means clustering. Basically, online recommendations, identification of data outliers, and segment text topics are all examples of unsupervised learning.

### **1.4.3 Semi Supervised Learning:**

As the name suggests, semi-supervised learning is a bit of both supervised and unsupervised learning and uses both labelled and unlabelled data for training. In a typical scenario, the algorithm would use a small amount of labelled data with a large amount of unlabelled data.

**Figure 1.4.3: Semi Supervised Learning**

# **CHAPTER 2**

## **DEEP LEARNING**

### **2.1 INTRODUCTION**

In statistical machine learning, a major issue is the selection of an appropriate feature space where input instances have desired properties for solving a particular problem. For example, in the context of supervised learning for binary classification, it is often required that the two classes are separable by a hyperplane.

### **2.2 IMPORTANCE OF DEEP LEARNING**

The ability to process large numbers of features makes deep learning very powerful when dealing with unstructured data. However, deep learning algorithms can be overkill for less complex problems because they require access to a vast amount of data to be effective. For instance, ImageNet, the common benchmark for training deep learning models for comprehensive image recognition, has access to over 14 million images.

If the data is too simple or incomplete, it is very easy for a deep learning model to become overfitted and fail to generalize well to new data. As a result, deep learning models are not as effective as other techniques (such as boosted decision trees or linear models) for most practical business problems such as understanding customer churn, detecting fraudulent transactions and other cases with smaller datasets and fewer features. In certain cases like multiclass\_classification, deep learning can work for smaller, structured datasets.

### **2.3 RELATION BETWEEN DATA MINING, MACHINE LEARNING, DEEP LEARNING**

Machine learning and data mining use the same algorithms and techniques as data mining, except the kinds of predictions vary. While data mining discovered previously unknown patterns and knowledge, machine learning reproduces known patterns and knowledge—and further automatically applies that information to data, decision-making, and actions.

Deep learning, on the other hand, uses advanced computing power and special types of neural networks and applies them to large amounts of data to learn, understand, and identify complicated patterns. Automatic language translation and medical diagnoses are examples of deep learning.

# CHAPTER 3

## PYTHON

Basic programming language used for machine learning is: PYTHON

### 3.1 INTRODUCTION TO PYTHON

- Python is a high-level, interpreted, interactive and object-oriented scripting language.
- Python is a general-purpose programming language that is often applied in scripting roles
- Python is Interpreted: Python is processed at runtime by the interpreter. You do not need to compile your program before executing it. This is like PERL and PHP.
- Python is Interactive: You can sit at a Python prompt and interact with the interpreter directly to write your programs.
- Python is Object-Oriented: Python supports the Object-Oriented style or technique of programming that encapsulates code within objects.

### 3.2 HISTORY OF PYTHON

- Python was developed by GUIDO VAN ROSSUM in early 1990's
- Its latest version is 3.7, it is generally called as python3.

### 3.3 FEATURES OF PYTHON

- Easy-to-learn: Python has few keywords, simple structure, and a clearly defined syntax, This allows the student to pick up the language quickly.
- Easy-to-read: Python code is more clearly defined and visible to the eyes.
- Easy-to-maintain: Python's source code is fairly easy-to-maintaining.
- A broad standard library: Python's bulk of the library is very portable and cross-platform compatible on UNIX, Windows, and Macintosh.
- Portable: Python can run on a wide variety of hardware platforms and has the same interface on all platforms.
- Extendable: You can add low-level modules to the Python interpreter. These modules

enable programmers to add to or customize their tools to be more efficient

- Databases: Python provides interfaces to all major commercial databases.
- GUI Programming: Python supports GUI applications that can be created and ported to many system calls, libraries and windows systems, such as Windows MFC, Macintosh, and the X Window system of Unix.

## 3.4 HOW TO SETUP PYTHON

- Python is available on a wide variety of platforms including Linux and Mac OS X.

Let's understand how to set up our Python environment.

- The most up-to-date and current source code, binaries, documentation, news, etc., is available on the official website of Python.

### 3.4.1 Installation (using python IDLE):

- Installing python is generally easy, and nowadays many Linux and Mac OS distributions include a recent python.
- Download python from [www.python.org](http://www.python.org)
- When the download is completed, double click the file and follow the instructions to install it.
- When python is installed, a program called IDLE is also installed along with it. It provides a graphical user interface to work with python.

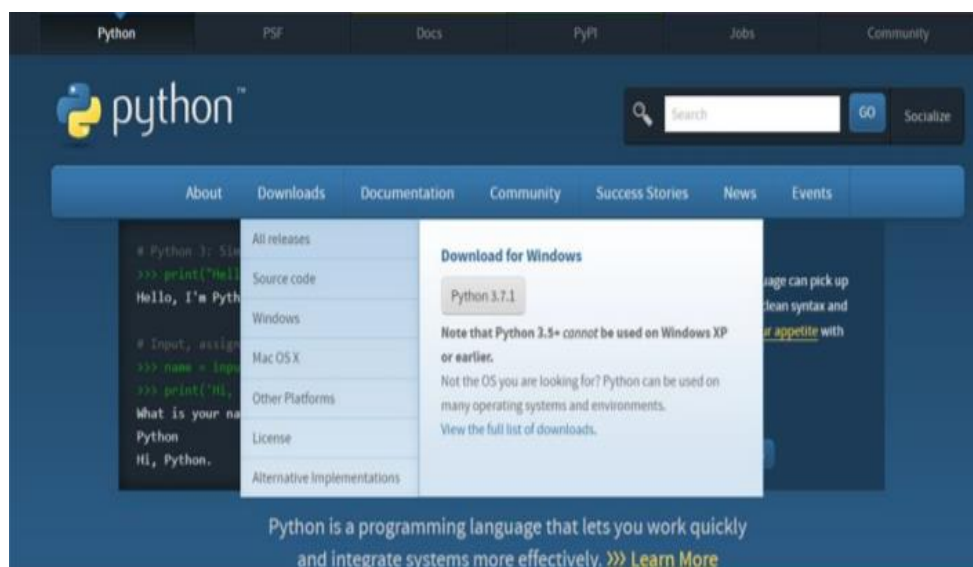

Figure 3.4.1: Python download

### 3.4.2 Installation (using Anaconda):

- Python programs are also executed using Anaconda.
- Anaconda is a free open source distribution of python for large scale data processing, predictive analytics and scientific computing.
- Conda is a package manager that quickly installs and manages packages.
- In WINDOWS:
  - Step 1: Open Anaconda.com/downloads in a web browser.
  - Step 2: Download python 3.4 version for (32-bits graphic installer/64 -bit graphic installer)
  - Step 3: select installation type (all users)
  - Step 4: Select path (i.e. add anaconda to path & register anaconda as default python 3.4) next click install and next click finish
  - Step 5: Open jupyter notebook (it opens in default browser)

Figure 3.4.2.1: Anaconda download

Figure 3.4.2.2: Jupyter notebook

## 3.5 PYTHON VARIABLE TYPES

- Variables are nothing but reserved memory locations to store values. This means that when you create a variable you reserve some space in memory.
- Variables are nothing but reserved memory locations to store values.
- Based on the data type of a variable, the interpreter allocates memory and decides what can be stored in the reserved memory.
- Python variables do not need explicit declaration to reserve memory space. The declaration happens automatically when you assign a value to a variable.
- Python has various standard data types that are used to define the operations possible on them and the storage method for each of them.
- Python has five standard data types –
  - o Numbers
  - o Strings
  - o Lists
  - o Tuples
  - o Dictionary

### 3.5.1 Python Numbers:

- Number data types store numeric values. Number objects are created when you assign a value to them.
- Python supports four different numerical types – int (signed integers) long (long integers, they can also be represented in octal and hexadecimal) float (floating point real values) complex (complex numbers).

### 3.5.2 Python Strings:

- Strings in Python are identified as a contiguous set of characters represented in the quotation marks.
- Python allows for either pairs of single or double quotes.
- Subsets of strings can be taken using the slice operator ([ ] and [:]) with indexes starting at 0 in the beginning of the string and working their way from -1 at the end.
- The plus (+) sign is the string concatenation operator and the asterisk (\*) is the repetition operator.

### 3.5.3 Python Lists:

- Lists are the most versatile of Python's compound data types.
- A list contains items separated by commas and enclosed within square brackets ([]).
- To some extent, lists are similar to arrays in C. One difference between them is that all the items belonging to a list can be of different data types.
- The values stored in a list can be accessed using the slice operator ([ ] and [:]) with indexes starting at 0 in the beginning of the list and working their way to end -1.
- The plus (+) sign is the list concatenation operator, and the asterisk (\*) is the repetition operator.

### 3.5.4 Python Tuples:

- A tuple is another sequence data type that is similar to the list.
- A tuple consists of a number of values separated by commas. Unlike lists, however, tuples are enclosed within parentheses.
- The main differences between the lists and the tuples are: Lists are enclosed in brackets ([ ]) and their elements and size can be changed, while tuples are enclosed in parentheses ( ( ) ) and cannot be updated.
- Tuples can be thought of as read-only lists.
- For example – Tuples are fixed size in nature whereas lists are dynamic. In other words, a tuple is immutable whereas a list is mutable. You can't add elements to a tuple. Tuples have no append or extend method. You can't remove elements from a tuple. Tuples have no remove or pop method.

### 3.5.5 Python Dictionary:

- Python's dictionaries are kind of hash table type. They work like associative arrays or hashes found in Perl and consist of key-value pairs. A dictionary key can be almost any Python type, but are usually numbers or strings. Values, on the other hand, can be any arbitrary Python object.
- Dictionaries are enclosed by curly braces ({ }) and values can be assigned and accessed using square braces ([]).
- You can use numbers to "index" into a list, meaning you can use numbers to find out what's in lists. You should know this about lists by now, but make sure you understand that you can only use numbers to get items out of a list.

- What a dict does is let you use anything, not just numbers. Yes, a dict associates one thing to another, no matter what it is.

## **3.6 PYTHON FUNCTION**

### **3.6.1 Defining a Function:**

You can define functions to provide the required functionality. Here are simple rules to define a function in Python. Function blocks begin with the keyword `def` followed by the function name and parentheses (i.e. `()`).

Any input parameters or arguments should be placed within these parentheses. You can also define parameters inside these parentheses. The code block within every function starts with a colon (`:`) and is indented. The statement `return [expression]` exits a function, optionally passing back an expression to the caller. A return statement with no arguments is the same as `return None`.

### **3.6.2 Calling a Function:**

Defining a function only gives it a name, specifies the parameters that are to be included in the function and structures the blocks of code. Once the basic structure of a function is finalized, you can execute it by calling it from another function or directly from the Python prompt.

## **3.7 PYTHON USING OOPs CONCEPTS**

### **3.7.1 Class:**

- **Class:** A user-defined prototype for an object that defines a set of attributes that characterize any object of the class. The attributes are data members (class variables and instance variables) and methods, accessed via dot notation.
- **Class variable:** A variable that is shared by all instances of a class. Class variables are defined within a class but outside any of the class's methods. Class variables are not used as frequently as instance variables are.
- **Data member:** A class variable or instance variable that holds data associated with a class and its objects.
- **Instance variable:** A variable that is defined inside a method and belongs only to the current instance of a class.

- Defining a Class:

- o We define a class in a very similar way how we define a function.
- o Just like a function ,we use parentheses and a colon after the class name(i.e. ()) when we define a class. Similarly, the body of our class is indented like a functions body is.

```
def my_function():  
    # the details of the  
    # function go here
```

```
class MyClass():  
    # the details of the  
    # class go here
```

**Figure 3.7.1: Defining a Class**

### 3.7.2 `__init__` method in Class:

- The init method — also called a constructor — is a special method that runs when an instance is created so we can perform any tasks to set up the instance.
- The init method has a special name that starts and ends with two underscores: `__init__` ().

## **CHAPTER 4**

### **CASE STUDY**

#### **4.1 PROBLEM STATEMENT**

To predict the Acceptance of Admission into a University using Machine Learning Algorithm called Multiple Linear Regression, Random Forest Regressor, Decision Tree Algorithm.

#### **4.2 DATA SET**

The given data set consists of the following parameters:

A - Serial No: A serial number is a unique identifier assigned incrementally or sequentially to an item, to uniquely identify it.

B - GRE Score: The Graduate Record Examination is a standardized exam, often required for admission to graduate and MBA programs globally.

C - TOEFL Score: The Test of English as a Foreign Language is a standardized test for non-native English speakers that are choosing to enrol in English-speaking universities.

D - University Rating: Rating of University based on different factors related to university.

E - SOP: Statement of Purpose is an essay stating the purpose of applying to a particular course in a particular university.

F - LOR: A letter of recommendation, also known as a letter of reference is a document in which the writer assesses the qualities, characteristics, and capabilities of the person being recommended in terms of that individual's ability to perform a particular task.

G - CGPA: Cumulative Grade Point Average refers to the overall GPA, which includes dividing the number of quality points earned in all courses attempted by the total degree-credit hours in all attempted courses.

H - Research: A careful consideration of study regarding a particular concern.

I - Chance of Admit: Chances for the admission into a University.

### **4.3 OBJECTIVE OF THE CASE STUDY**

The main objective of the project was to develop a system that can help the admission committee of the university to make better and faster decisions. Created a similar model to predict the enrolment of the student in the university based on the factors like GRE score, GPA score etc. To get a better understanding and chalking out a plan of action for solution of the student, we have adapted the viewpoint of looking at categories and for further deep understanding of the problem, we have also considered SOP, LOR, Research features.

# CHAPTER 5

## MODEL BUILDING

### 5.1 PREPROCESSING OF THE DATA

Pre-processing of the data actually involves the following steps:

#### 5.1.1 GETTING THE DATASET:

We can get the data set from the database or we can get the data from the client.

#### 5.1.2 IMPORTING THE LIBRARIES:

We have to import the libraries as per the requirement of the algorithm.

#### Importing the Libraries

```
import pandas as pd
import numpy as np
import matplotlib.pyplot as plt
import seaborn as sns
import statsmodels.api as sm
```

Figure 5.1.2: Importing Libraries

#### 5.1.3 IMPORTING THE DATA-SET:

Pandas in python provide an interesting method `read_csv()`. The `read_csv` function reads the entire dataset from a comma separated values file and we can assign it to a Data Frame to which all the operations can be performed. It helps us to access each and every row as well as columns and each and every value can be accessed using the data frame. Any missing value or NaN value has to be cleaned.

## Reading the Data Set

```
data = pd.read_csv("Admission_Predict.csv") #Data Loading
data.head()
```

	Serial No.	GRE Score	TOEFL Score	University Rating	SOP	LOR	CGPA	Research	Chance of Admit
0	1	337	118	4	4.5	4.5	9.65	1	0.92
1	2	324	107	4	4.0	4.5	8.87	1	0.76
2	3	316	104	3	3.0	3.5	8.00	1	0.72
3	4	322	110	3	3.5	2.5	8.67	1	0.80
4	5	314	103	2	2.0	3.0	8.21	0	0.65

Figure 5.1.3: Reading the dataset

### 5.1.4 HANDLING MISSING VALUES:

Missing values can be handled in many ways using some inbuilt methods:

(a)dropna(): dropna() is a function which drops all the rows and columns which are having the missing values (i.e. NaN)

```
data.dropna()
```

	no	gre	toefl	rating	sop	lor	gpa	research	chance
0	1	337	118	4	4.5	4.5	9.65	1	0.92
1	2	324	107	4	4.0	4.5	8.87	1	0.76
2	3	316	104	3	3.0	3.5	8.00	1	0.72
3	4	322	110	3	3.5	2.5	8.67	1	0.80
4	5	314	103	2	2.0	3.0	8.21	0	0.65
...	...	...	...	...	...	...	...	...	...
395	396	324	110	3	3.5	3.5	9.04	1	0.82
396	397	325	107	3	3.0	3.5	9.11	1	0.84
397	398	330	116	4	5.0	4.5	9.45	1	0.91
398	399	312	103	3	3.5	4.0	8.78	0	0.67
399	400	333	117	4	5.0	4.0	9.66	1	0.95

400 rows × 9 columns

Figure 5.1.4.1: data after using dropna()

- dropna() function has a parameter called how which works as follows
- if how = 'all' is passed then it drops the rows where all the columns of the Particular row is missing

- if `how = 'any'` is passed then it drops the rows where all the columns of the particular row is missing

(b)`fillna()`: `fillna()` is a function which replaces all the missing values using different ways.

```
data.fillna(0)
```

	no	gre	toefl	rating	sop	lor	gpa	research	chance
0	1	337	118	4	4.5	4.5	9.65	1	0.92
1	2	324	107	4	4.0	4.5	8.87	1	0.76
2	3	316	104	3	3.0	3.5	8.00	1	0.72
3	4	322	110	3	3.5	2.5	8.67	1	0.80
4	5	314	103	2	2.0	3.0	8.21	0	0.65
...	...	...	...	...	...	...	...	...	...
395	396	324	110	3	3.5	3.5	9.04	1	0.82
396	397	325	107	3	3.0	3.5	9.11	1	0.84
397	398	330	116	4	5.0	4.5	9.45	1	0.91
398	399	312	103	3	3.5	4.0	8.78	0	0.67
399	400	333	117	4	5.0	4.0	9.66	1	0.95

400 rows × 9 columns

**Figure 5.1.4.2: functioning of `fillna(0)`**

- `fillna()` also have parameters called `method` and `axis`
- if we use `method = 'ffill'` where `ffill` is a method called forward fill, which carry forwards the previous row's value
- if we use `method = 'bfill'` where `bfill` is a method called backward fill, which carry backward the next row's value
- if we use `method = 'ffill'`, `axis = 'columns'` then it carries forwards the previous column's value
- if we use `method = 'bfill'`, `axis = 'columns'` then it carries backward the next column's value

(c)interpolate(): interpolate() is a function which comes up with a guess value based on the other values in the dataset and fills those guess values in the place of missing values.

```
data.interpolate()
```

	no	gre	toefl	rating	sop	lor	gpa	research	chance
0	1	337	118	4	4.5	4.5	9.65	1	0.92
1	2	324	107	4	4.0	4.5	8.87	1	0.76
2	3	316	104	3	3.0	3.5	8.00	1	0.72
3	4	322	110	3	3.5	2.5	8.67	1	0.80
4	5	314	103	2	2.0	3.0	8.21	0	0.65
...	...	...	...	...	...	...	...	...	...

**Figure 5.1.4.3: functioning of interpolate()**

(d)mean and median imputation

- mean and median imputation can be performed by using fillna().
- mean imputation calculates the mean for the entire column and replaces the missing values in that column with the calculated mean.
- median imputation calculates the median for the entire column and replaces the missing values in that column with the calculated median.

```
data.fillna(data.mean())
```

	no	gre	toefl	rating	sop	lor	gpa	research	chance
0	1	337	118	4	4.5	4.5	9.65	1	0.92
1	2	324	107	4	4.0	4.5	8.87	1	0.76
2	3	316	104	3	3.0	3.5	8.00	1	0.72
3	4	322	110	3	3.5	2.5	8.67	1	0.80
4	5	314	103	2	2.0	3.0	8.21	0	0.65
...	...	...	...	...	...	...	...	...	...

**Figure 5.1.4.4: mean imputation**

```
data.fillna(data.median())
```

	no	gre	toefl	rating	sop	lor	gpa	research	chance
0	1	337	118	4	4.5	4.5	9.65	1	0.92

2	3	316	104	3	3.0	3.5	8.00	1	0.72
3	4	322	110	3	3.5	2.5	8.67	1	0.80
4	5	314	103	2	2.0	3.0	8.21	0	0.65
...	...	...	...	...	...	...	...	...	...

**Figure 5.1.4.5: median imputation**

### 5.1.5 CATEGORICAL DATA:

- Machine Learning models are based on equations, we need to replace the text by numbers. So that we can include the numbers in the equations.
- Categorical Variables are of two types: Nominal and Ordinal
- Nominal: The categories do not have any numeric ordering in between them. They don't have any ordered relationship between each of them. Examples: Male or Female, any colour
- Ordinal: The categories have a numerical ordering in between them. Example: Graduate is less than Post Graduate, Post Graduate is less than Ph.D. customer satisfaction survey, high low medium
- Categorical data can be handled by using dummy variables, which are also called as indicator variables.
- Handling categorical data using dummies: In pandas library we have a method called `get_dummies()` which creates dummy variables for those categorical data in the form of 0's and 1's. Once these dummies got created, we have to concat this dummy set to our data frame or we can add that dummy set to the data frame.

## 5.2 Exploratory Data Analysis

`describe()`: This method computes a summary of statistics like count, mean, standard deviation, min, max, and quartile.

```
data.describe()
```

	no	gre	toefl	rating	sop	lor	gpa	research	chance
count	400.000000	400.000000	400.000000	400.000000	400.000000	400.000000	400.000000	400.000000	400.000000
mean	200.500000	316.807500	107.410000	3.087500	3.400000	3.452500	8.598925	0.547500	0.724350
std	115.614301	11.473646	6.069514	1.143728	1.006869	0.898478	0.596317	0.498362	0.142609
min	1.000000	290.000000	92.000000	1.000000	1.000000	1.000000	6.800000	0.000000	0.340000
25%	100.750000	308.000000	103.000000	2.000000	2.500000	3.000000	8.170000	0.000000	0.640000
50%	200.500000	317.000000	107.000000	3.000000	3.500000	3.500000	8.610000	1.000000	0.730000
75%	300.250000	325.000000	112.000000	4.000000	4.000000	4.000000	9.062500	1.000000	0.830000
max	400.000000	340.000000	120.000000	5.000000	5.000000	5.000000	9.920000	1.000000	0.970000

**Figure 5.2.1: describing the data**

`shape`: This gives the number of columns and rows.

```
data.shape  
(400, 9)
```

**Figure 5.2.2: showing no. of columns and rows**

`columns`: This gives all the column names of the Data set.

```
data.columns  
Index(['no', 'gre', 'toefl', 'rating', 'sop', 'lor', 'gpa', 'research',  
       'chance'],  
      dtype='object')
```

**Figure 5.2.3: column names of data set**

## 5.3 Data Visualization

### 5.3.1 Histogram of Admission Chance:

A histogram is a graphical representation that organizes a group of data points into user-specified ranges. It is similar in appearance to a bar graph. The histogram condenses a data series into an easily interpreted visual by taking many data points and grouping them into logical ranges or bins.

**Figure 5.3.1: Histogram of Admission Chance**

Histogram shows us that 'chance of admission' column is well distributed in data. It seems to have more chance of admission from between 0.7 to 0.8 Frequency.

### 5.3.2 Line Plot for Research Output and The Chance of Admission:

A line plot or line graph is a type of plot which displays information as a series of data points called 'markers' connected by straight line segments. I call it line.py and import matplotlib library in it. import matplotlib.pyplot as plt. The alias plt has been set for simplification purpose.

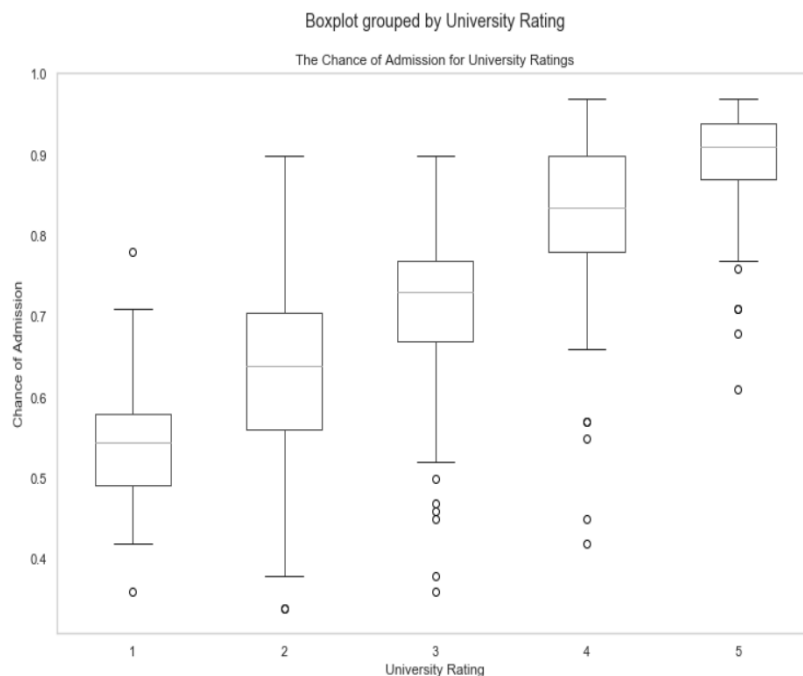

**Figure 5.3.2: Line Plot for Research and The Chance of Admission**

The chance of admission depends a great deal on the subject's research output, hence research can be a good predictor in predicting the outcome.

### 5.3.3 Box Plot of University Rating and The Chance of Admission:

Boxplots are a measure of how well distributed the data in a data set is. It divides the data set into three quartiles. This graph represents the minimum, maximum, median, first quartile and third quartile in the data set.

```
#A box plot is a method for graphically depicting groups of numerical data through their quartiles.  
data.boxplot(column='Chance of Admit',by='University Rating',grid=False,figsize=(12,8))  
plt.title('The Chance of Admission for University Ratings')  
plt.xlabel('University Rating')  
plt.ylabel('Chance of Admission')  
plt.show()
```

**Figure 5.3.3: Box Plot of University Rating and The Chance of Admission**

As it can be seen from the boxplot chart, chance of admission is higher within the applicants of lower rated (5) universities. A box plot is a method for graphically depicting groups of numerical data through their quartiles. The box extends from the Q1 to Q3 quartile values of the data, with a line at the median (Q2). The whiskers extend from the edges of box to show the range of the data.

## 5.4 TRAINING THE MODEL

- Splitting the data: after the pre-processing is done then the data is split into train and test sets
- In Machine Learning in order to access the performance of the classifier. You train the classifier using 'training set' and then test the performance of your classifier on unseen 'test set'. An important point to note is that during training the classifier only uses the training set. The test set must not be used during training the classifier. The test set will only be available during testing the classifier.
- training set - a subset to train a model. (Model learns patterns between Input and Output).
- test set - a subset to test the trained model. (To test whether the model has correctly learnt).
- The amount or percentage of Splitting can be taken as specified (i.e. train data = 75%, test data = 25% or train data = 80%, test data = 20%).
- First, we need to identify the input and output variables and we need to separate the input set and output set.
- In scikit learn library we have a package called model selection in which train\_test\_split method is available. we need to import this method.
- This method splits the input and output data to train and test based on the percentage specified by the user and assigns them to four different variables (we need to mention the variables).
- Then we need to import linear regression.

```
from sklearn.model_selection import train_test_split

X_train,X_test,y_train,y_test =train_test_split(X,Y,test_size=0.2,random_state=42)
```

**Figure 5.4.1: importing train\_test\_split**

- Then we need to import linear regression method from linear model package from scikit learn library
- We need to train the model based on our train set (that we have obtained from splitting)
- Then we have to test the model for the test set, that is done as follows
- We have a method called predict, using this method we need to predict the output for input test set and we need to compare the output with the output test data.
- If the predicted values and the original values are close then we can say that the model is trained with good accuracy.

#### Correlation:

- Correlation is a statistical technique that can show whether and how strongly pairs of variables are related. Correlation is described as the analysis which lets us know the association or the absence of the relationship between two variables 'x' and 'y'. It is a statistical measure that represents the strength of the connection between pairs of variables.
- We can also find the column which is affecting the R-Squared value so that we can perform operations on that specific column or we can remove that column, this can be done using pair plot.
- In pair plot we need to find the correlation between two variables and we can do some operations on that variables
- Pair plot is a method which is available in seaborn library, so to use this pair plot method we have to import seaborn library.

```
correlation = data.corr()
```

Figure 5.4.2: Correlation

Pair plot allows to see both distribution of single variables and relationship between two variables.

```
sns.pairplot(data)
```

```
<seaborn.axisgrid.PairGrid at 0x1f2ce662f08>
```

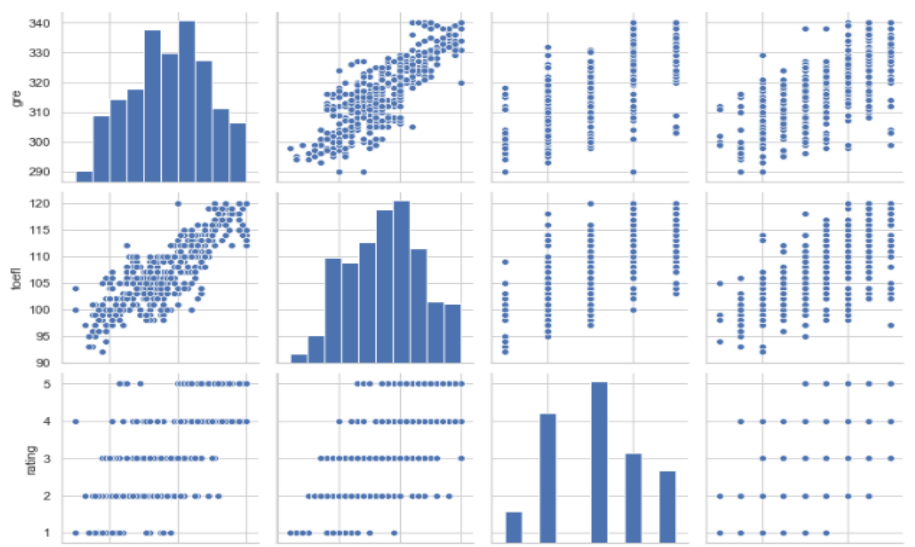

Figure 5.4.3: pair plot

# CHAPTER 6

## EVALUATING THE CASE STUDY:

### 6.1 MULTIPLE LINEAR REGRESSION

A multiple linear regression model allows us to capture the relationship between multiple feature columns and the target column. Here's what the formula looks like:

$$y^{\wedge}=a_0+a_1x_1+a_2x_2+\dots+a_nx_n$$

- Importing the required libraries

```
import pandas as pd
import numpy as np
import matplotlib.pyplot as plt
import seaborn as sns
import statsmodels.api as sm
```

Figure 6.1.1: Importing the libraries

- Reading the Data-Set

#### Reading the Data Set

```
data = pd.read_csv("Admission_Predict.csv") #Data Loading
data.head()
```

	Serial No.	GRE Score	TOEFL Score	University Rating	SOP	LOR	CGPA	Research	Chance of Admit
0	1	337	118	4	4.5	4.5	9.65	1	0.92
1	2	324	107	4	4.0	4.5	8.87	1	0.76
2	3	316	104	3	3.0	3.5	8.00	1	0.72
3	4	322	110	3	3.5	2.5	8.67	1	0.80
4	5	314	103	2	2.0	3.0	8.21	0	0.65

Figure 6.1.2: Reading the Data-Set

- Handling the missing values. There is a method called `isnull()` which gives the number of missing values in each and every column.

```
data.isnull().sum() #There are no missing values in the data.
```

```
gre      0
toefl    0
rating   0
sop      0
lor      0
gpa      0
research 0
chance   0
dtype: int64
```

**Figure 6.1.3: After handling the missing values**

- Removing the columns which are not required using drop method

```
data = data.drop("no", axis=1) #drop the serial number column
data.head()
```

	gre	toefl	rating	sop	lor	gpa	research	chance
0	337	118	4	4.5	4.5	9.65	1	0.92
1	324	107	4	4.0	4.5	8.87	1	0.76
2	316	104	3	3.0	3.5	8.00	1	0.72
3	322	110	3	3.5	2.5	8.67	1	0.80
4	314	103	2	2.0	3.0	8.21	0	0.65

**Figure 6.1.4: dropping the columns which are not required**

- Heatmap: The heatmap is a way of representing data in a two-dimensional form. The data values are represented in colours in the graph. The aim of heatmap is to provide a coloured visual summary of the information.

```
fig, ax = plt.subplots(figsize=(8,8))
sns.heatmap(data.corr(), annot=True, cmap='Blues')

<matplotlib.axes._subplots.AxesSubplot at 0x20164bbb5c8>
```

**Figure 6.1.5: Heatmap Visualization**

- Data normalization is important in order to represent data in comparable scales.

```
scaler = StandardScaler()
X_train = scaler.fit_transform(X_train)
X_test = scaler.fit_transform(X_test)
```

**Figure 6.1.6: Data Normalization**

### 6.1.1 Building the model (using splitting):

- First, we have to retrieve the input and output sets from the given dataset
- Import the train\_test\_split from model selection package from scikit learn library
- Then assigning the output to four different variables, before assigning we have to mention the train size or test size as a parameter to train\_test\_split. Then this method will split according to the size and assigns it to four variables.

```
print(X_train.shape)
print(X_test.shape)
print(y_train.shape)
print(y_test.shape)
```

```
(320, 7)
(80, 7)
(320,)
(80,)
```

**Figure 6.1.1.1: Splitting the data**

- Import linear regression method which is available in linear model package from scikit learn library

```
linreg = LinearRegression()
linreg.fit(X_train, y_train)
y_predict = linreg.predict(X_test)
linreg_score = (linreg.score(X_test, y_test))*100
linreg_score|
```

```
81.73867881114431
```

**Figure 6.1.1.2: Importing linear regression**

- Once the model is built, we need to check for accuracy.
- This can be done using the predict method which is used to predict the output for input test set, and compare the predicted output with original output test set.

```

pred=linreg.predict(X_test)
pred

array([0.64960648, 0.71738274, 0.91774571, 0.81014755, 0.58223945,

0.720625
```

**Figure 6.1.1.4: Comparing with original output**

- Computing the metrics for mean absolute error, mean squared error, root mean squared error, and R-squared, and put them into a Data Frame.

```

## Test the model on testing data
y_pred = linreg.predict(X_test) # test data--> unseen data
y_pred
## We need to compare the actual values(y_test) and the predicted
                                #values(y_test_pred)

from sklearn.metrics import r2_score, mean_absolute_error, mean_squared_error
print('R^2:', r2_score(y_test,y_pred))

print('Adjusted R^2:', 1- (1-r2_score(y_test, y_pred))*(len(X_test)-1)/
                        (len(X_test)-X_test.shape[1]-1))

print('MAE:', mean_absolute_error(y_test, y_pred))

print('MSE:', mean_squared_error(y_test, y_pred))

R^2: 0.817386788111443
Adjusted R^2: 0.7996327258445
MAE: 0.05013672161921001
MSE: 0.0047156865972212275

```

**Figure 6.1.1.5: Getting R-squared value**

## Linear Regression Accuracy

```

#Linear Regression Accuracy
linreg_score = (linreg.score(X_test,y_test))*100
linreg_score

81.73867881114431

```

**Figure 6.1.1.6: Linear Regression Accuracy**

The Linear Regression Accuracy is 81.73

## 6.2 Random Forest

Every decision tree has high variance, but when we combine all of them together in parallel then the resultant variance is low as each decision tree gets perfectly trained on that particular sample data and hence the output doesn't depend on one decision tree but multiple decision trees. In the case of a classification problem, the final output is taken by using the majority voting classifier. In the case of a regression problem, the final output is the mean of all the outputs. This part is Aggregation.

I have used a random forest algorithm for solving this regression problem. The random forest combines hundreds or thousands of decision trees, trains each one on a slightly different set of the observations, splitting nodes in each tree considering a limited number of the features. The final predictions of the random forest are made by averaging the predictions of each individual tree.

`n_estimators` is the number of trees to be used in the forest. Since Random Forest is an ensemble method consisting of creating multiple decision trees, this parameter is used to control the number of trees to be used in the process.

```
from sklearn.ensemble import RandomForestRegressor
from sklearn.metrics import mean_absolute_error
```

**Figure 6.2.1: Importing Random Forest Regressor**

```
from sklearn import metrics
print('MAE:', mean_absolute_error(y_test, y_pred))

print('MSE:', mean_squared_error(y_test, y_pred))

print('RMSE', np.sqrt(mean_squared_error(y_test, y_pred)))
```

MAE: 0.050737499999999935  
MSE: 0.004913828249999997  
RMSE 0.0700987036256734

### Random Forest Accuracy

```
forest = RandomForestRegressor(n_estimators=110,max_depth=6,random_state=0)
forest.fit(X_train, y_train)
y_predict = forest.predict(X_test)
forest_score = (forest.score(X_test, y_test))*100
forest_score
```

81.35407137081936

**Figure 6.2.2: Random Forest Accuracy**

The Accuracy of Random Forest regressor is 81.35.

## 6.3 Decision Tree

Decision Tree is a decision-making tool that uses a flowchart-like tree structure or is a model of decisions and all of their possible results, including outcomes, input costs and utility. Decision-tree algorithms fall under the category of supervised learning algorithms. It works for both continuous as well as categorical output variables.

## Decision Tree Accuracy

```
dec_tree = DecisionTreeRegressor(random_state=0, max_depth=6)
dec_tree.fit(X_train, y_train)
y_predict = dec_tree.predict(X_test)
dec_tree_score = (dec_tree.score(X_test, y_test))*100
dec_tree_score
```

73.99851580517213

Figure 6.3.1: Decision Tree Accuracy

## 6.4 Comparing all the Accuracies

Among the two algorithms, Multiple Linear Regression gives the best accuracy result.

```
#Comparing Scores
Methods = ['Linear Regression', 'Random Forests']
Scores = np.array([linreg_score, forest_score])

fig, ax = plt.subplots(figsize=(8,6))
sns.barplot(Methods, Scores)
plt.bar(Methods, Scores, color=['red', 'teal'])
plt.title('Algorithm Prediction Accuracies')
plt.ylabel('Accuracy')
Text(0, 0.5, 'Accuracy')
```

Figure 6.4.1: Comparison of Accuracies

From the above graph, it is conformed that liner regression gives the highest accuracy among the algorithms that are used in prediction of acceptance of admission into a university.

## 6.5 Raw Data

Raw data is the data that is measured and collected directly from machine, web, etc. The processed data is the type of data that is processed from raw data. Usually some kind of cleaning, transformation are performed to convert the raw data into a format that can be analysed and visualized.

The given data set consists of the following parameters:

A - Serial No: A serial number is a unique identifier assigned incrementally or sequentially to an item, to uniquely identify it.

B - GRE Score: The Graduate Record Examination is a standardized exam, often required for admission to graduate and MBA programs globally.

C - TOEFL Score: The Test of English as a Foreign Language is a standardized test for non-native English speakers that are choosing to enrol in English-speaking universities.

D - University Rating: Rating of University based on different factors related to university.

E - SOP: Statement of Purpose is an essay stating the purpose of applying to a particular course in a particular university.

F - LOR: A letter of recommendation, also known as a letter of reference is a document in which the writer assesses the qualities, characteristics, and capabilities of the person being recommended in terms of that individual's ability to perform a particular task.

G - CGPA: Cumulative Grade Point Average refers to the overall GPA, which includes dividing the number of quality points earned in all courses attempted by the total degree-credit hours in all attempted courses.

H - Research: A careful consideration of study regarding a particular concern.

I - Chance of Admit: Chances for the admission into a University.

```
print(linreg.predict([[327,111,4,4,4.5,9,1]]))
```

```
[10.12474609]
```

```
print(linreg.predict([[322,109,5,4.5,3.5,8.8,0]]))
```

```
[9.95657508]
```

```
print(linreg.predict([[338,118,4,3,4.5,9.4,1]]))
```

```
[10.4977254]
```

**Figure 6.5.1: Raw data**

Raw data (sometimes called source data or atomic data) is data that has not been processed for use. A distinction is sometimes made between data and information to the effect that information is the end product of data processing.

## CONCLUSION

It is concluded after performing thorough Exploratory Data analysis which include Splitting models which are computed to get accuracy and also Heat maps which are computed to get a clear understanding of the data set (which parameter has most abundant effect on the study case) and it's come to point of getting the solution for the problem statement being, Clearly CGPA is the most important criteria for graduate admission followed by GRE and TOEFL score.

For selecting the best algorithm,

- Linear Regression - 81.74%
- Random Forests - 81.35%
- Decision Trees - 73.99%

It seems that Linear Regression is the most accurate of the 3 methods and will be used to predict the future applicant's chances of admission.

Among the algorithms, Linear Regression gives the best Accuracy.

As a quick summary, I used multiple linear regression algorithm and random forest algorithm to visualize the importance of each features for graduate admission. This could be of great help for students preparing for their higher studies.
